

PREDICTION: The metal hooks could become unbent under excessive weight, posing an IMPACT risk because the load may fall abruptly, causing injury.

WHAT FAILED: 2
HOW IT FAILED: 2

WHAT FAILED: "The 'what_failed' component in the recall is 'length adjustment buckles,' while the prediction mentions 'metal hooks.' These are related parts as they both serve a function in securing or adjusting the load, hence a score of 2.

HOW IT FAILED: For 'how_failed,' the recall describes the buckles releasing unexpectedly, while the prediction describes the hooks becoming unbent under excessive weight. Both involve a failure leading to the load falling, but the mechanisms differ slightly, so a score of 2 is appropriate.

PREDICTION: The fabric straps could tear due to material fatigue, posing a CRASH risk as the load is no longer securely held, potentially causing it to fall.

CATEGORY: CRASH

WHAT FAILED: 2
HOW IT FAILED: 2

WHAT FAILED: The 'what failed' component in the recall is the 'length adjustment buckles,' while the prediction mentions 'fabric straps.' These are related parts as they are both part of the system that secures the load, but they are not the exact same component, hence a score of 2.

HOW IT FAILED:For 'how it failed,' the recall describes the buckles releasing unexpectedly, while the prediction describes the straps tearing due to material fatigue. Both involve a failure that results in the load not being securely held, but the mechanisms are different (release vs. tear), so they are related but not exact, resulting in a score of 2.

PREDICTION: The plastic buckle could break under stress, posing a FALLING risk because it may fail to retain the secured load.

CATEGORY: FALLING

WHAT FAILED: 2
HOW IT FAILED: 2

WHAT FAILED: "The 'what failed' component in the recall is the 'length adjustment buckles,' while the prediction mentions a 'plastic buckle.' These are related parts as they both refer to buckles, but the recall specifies a particular type of buckle, hence a score of 2.

HOW IT FAILED: For 'how it failed,' the recall describes the buckles releasing unexpectedly, while the prediction describes the buckle breaking under stress. Both describe a failure leading to a falling risk, but the mechanisms differ slightly: one is a release, and the other is a break, thus a score of 2.
